The Atlant c surfclam f shery, which spans the Northeast U.S. shelf, is among the most exposed to impacts from of shore wind energy development due to port location, overlap of fishing grounds and wind lease areas, and fishing pract ces. The assessment survey for surfclams is conducted on a commercial vessel and occupies stat ons that overlap of shore wind areas. Once of shore wind farm infrastructure is installed, assessment survey operations within wind farms may be curtailed or eliminated due to limits on vessel access, safety requirements, and assessment protocols. Excluding survey operations in certain areas could interrupt long-term survey time series, af ecting stock assessments by increasing uncertainty in biomass est mates and other parameters used in project ng f shery quotas. An agent-based modeling framework that integrates spat all dynamics in surfdam stock biology, f shery captain and feet behavior, and federal survey and management decisions was implemented to invest gate the impact of excluding wind farm leases from the federal survey and populat on assessment. Simulations were designed to compare assessment est mates of key biological reference points under conditions where the survey is excluded from planned and future wind farm lease areas. Integrated ecological-economic f sheries models, such as the one used in this study to assess a single species f sheries survey, provide a basis for understanding the impact of of shore wind on populat on assessments that are crit cal for resource management.

Dr. Borset is the Commercial Fisheries Specialist at the Virginia Inst tute of Marine Science (VIMS), where her work focuses on applied research to help meet the needs of the commercial f shing industry in Virginia. Her research interests focus on understanding the interact ons between populat on
